Assignment 4 - Helper Functions

Samuel Steiner -- Assignment 4 --- Association Rules

We begin by including the functions to generate frequent itemsets (via the Apriori algorithm) and resulting association rules:

To load our dataset of grocery transactions, use the command below

In [ ]:
```
dataset = load_dataset('grocery.csv')
D = list(map(set, dataset))
```

```
/Users/sam/opt/anaconda3/lib/python3.9/site-packages/numpy/core/_asarray.py:102: VisibleDeprecationWarning: Creating an ndar
ray from ragged nested sequences (which is a list-or-tuple of lists-or-tuples-or ndarrays with different lengths or shapes)
is deprecated. If you meant to do this, you must specify 'dtype=object' when creating the ndarray.
  return array(a, dtype, copy=False, order=order)
```

dataset is now a ndarray containing each of the 9835 transactions

In [ ]:
```
type(dataset)
```

Out[ ]:
```
numpy.ndarray
```

In [ ]:
```
dataset.shape
```

Out[ ]:
```
(9835,)
```

In [ ]:
```
dataset[0]
```

Out[ ]:
```
['citrus fruit', 'semi-finished bread', 'margarine', 'ready soups']
```

In [ ]:
```
dataset[1]
```

Out[ ]:
```
['tropical fruit', 'yogurt', 'coffee']
```

D Contains that dataset in a set format (which excludes duplicated items and sorts them)

In [ ]:
```
type(D[0])
```

Out[ ]:
```
set
```

In [ ]:
```
D[0]
```

Out[ ]:
```
{'citrus fruit', 'margarine', 'ready soups', 'semi-finished bread'}
```

Complete the assignment below by making use of the provided funtions.

You may use the notebook file attached with lesson 3 as a reference

```

Using the provided code for apriori makes this step simple, once the code was loaded I made it simple to experiment with the support and confidence variables by using a tuple to describe them. From there I experimented with values close to those in the directions for this assignement for part 3, .02 and .3 respectively. I found that there was a lot of information to gather from the data and since the data had ten thousand entries the seemingly low support values still had a large count. 1% of 10000 is 100 transactions. Looking at 5% or 500 transactions awith the same confidence value as part 3 generated only 3 rules.

```

The provided code again made this section relatively easy! The big thing I wanted to see here was if the rules that were generated were the same, to ensure the implementation was correct. This was the case. With the experimentation around this done it was easy to move onto the next step.

For part 3 to find the intrest factor I was able to substitute lift which was cheaper to calculate as all the values necessary were already calculated and needed less lookups. The reason this is possible is because the transactional data is binary, either the product is purchased or it is not purchased. Moving on to the 5 rules which were generated by sorting the rules by confidence, support, or intrest factor.

- First off when it comes to support, I found it unsuprising that these rules seem to be 1 item to 1 item rules as the number of transactions that contain a pair of items will always be more than a set of 3 items as or more.
- Second, intrestingly there was no rule which overlapped on all 3 tables. There was overlap for support and intrest factor as well as confidence and intrest factor but no support and confidence. Its not supprising as intrest factor is a composite variable made from the confidence and support.

The overlapping rules are as followed:

rule	table 1	table 2
[whole milk, root vegetables] ---> [other vegetables]	confidence	interest factor
[root vegetables] ---> [other vegetables]	support	interest factor
